Data Modelling and Form Design for a Business Application in Zoho Creator

Event Registration Application — Low-Code Development Report

Name	samyuktha
Roll Number	241401091
Department	csbs
Year of Study	3rd year 5th sem

Aim

To design a relational data model and build the corresponding online forms for a business Event Registration application using Zoho Creator, a low-code application development platform, and to verify that the deployed forms correctly capture, validate, and store participant, event, and session information.

Procedure / Steps Involved

The application was built in Zoho Creator by first setting up a blank application workspace, then designing the registration form with suitable field types, adding validation and mandatory rules, deploying the form as a live application, testing it with sample data, and finally verifying the stored records in the underlying database. The overall data model connecting all forms was then documented as an Entity-Relationship (ER) diagram. Each step is described below with its corresponding screenshot.

Step 1 — Create the Application Workspace

A new application, **"Event Registration"**, was created in Zoho Creator using the "From Scratch" option. This gave complete control over the fields and layout instead of relying on a pre-built template, and opened the application workspace where all subsequent configuration and development tools are accessed.

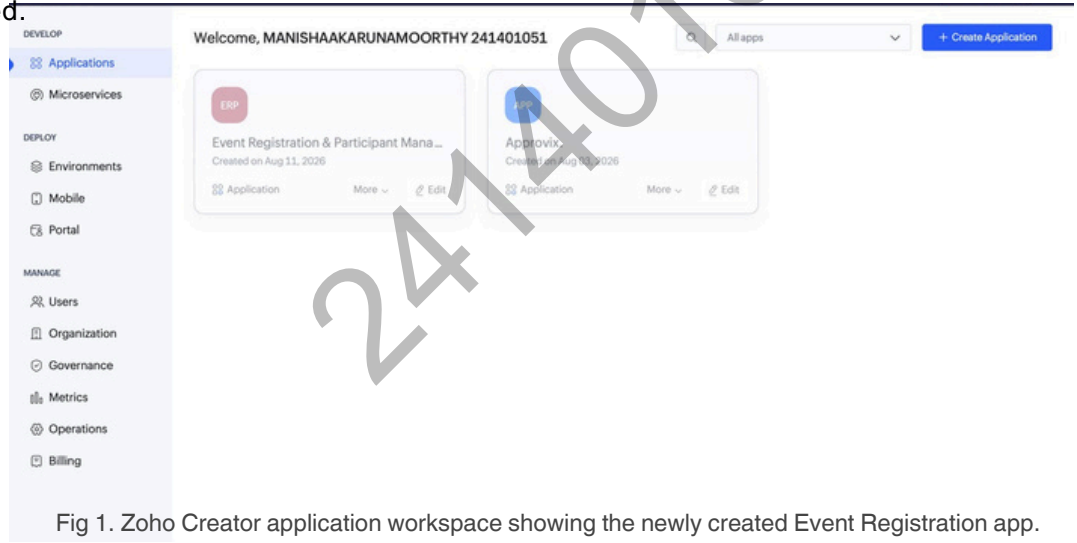

Fig 1. Zoho Creator application workspace showing the newly created Event Registration app.

Step 2 — Design the Registration Form and Configure Fields

The registration form was built field-by-field, matching each field type to the kind of data expected: Participant Name used First/Last Name sub-fields, Participant Type used Radio buttons (Student / Faculty / Professional), Team Size used a Number field, Email Address and Contact Number captured communication details, College/Organization Name used a Single Line field, and Institution Address used a Multi-line field.

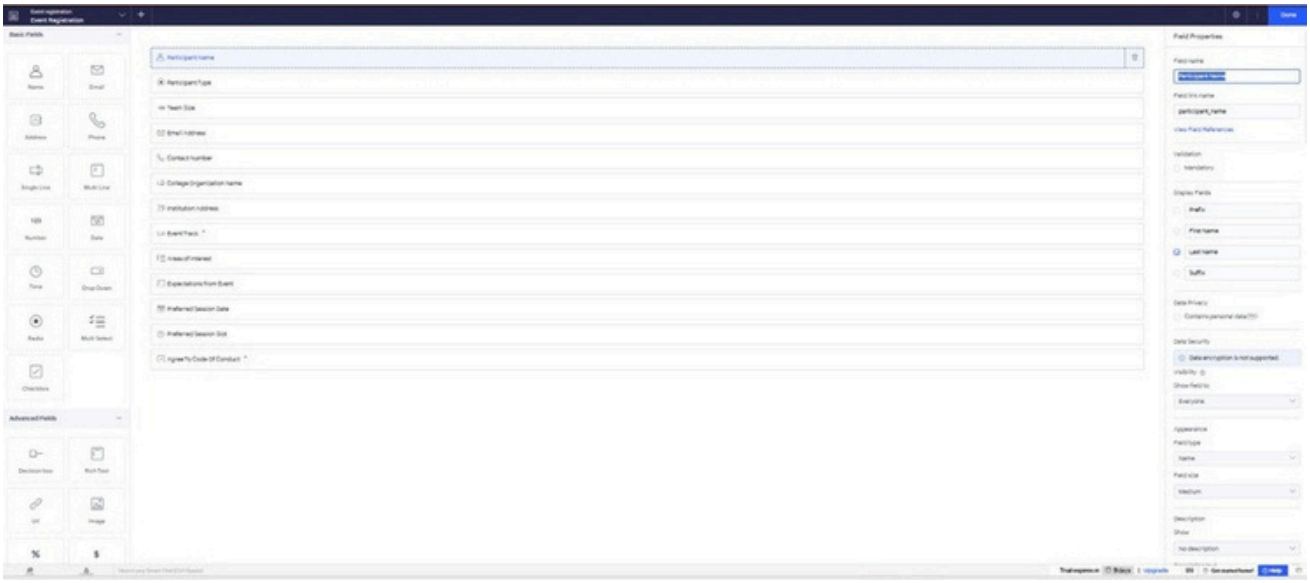

Fig 2. Form builder view with all configured fields listed in the Event Registration form.

Step 3 — Add Registration Requirements and Validation

Event-specific fields were added:EventTrack as a mandatoryDropdown, Areas of Interest and Expectations as descriptive text fields, Preferred Session Date/Slot as Dropdowns, and a mandatory Code of Conduct Checkbox. Mandatory settings were applied only to essential fields, ensuring complete registrations without over-restricting the form.

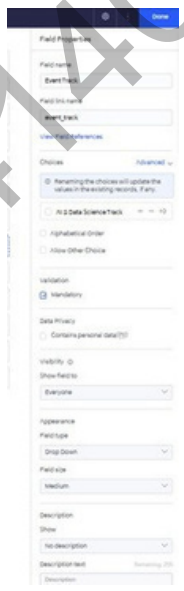

Fig 3. Field properties panel showing the Event Track field configured as a mandatory Dropdown.

Step 4 — Deploy the Application as a Live Form

Usingthe “Access thisapplication”option,the form was published as a live, user-facing page, separate from the form-builder workspace. The live version was reviewed to confirm that field order, labels, choices, and mandatory settings matched the intended design before it was used for actual data entry.

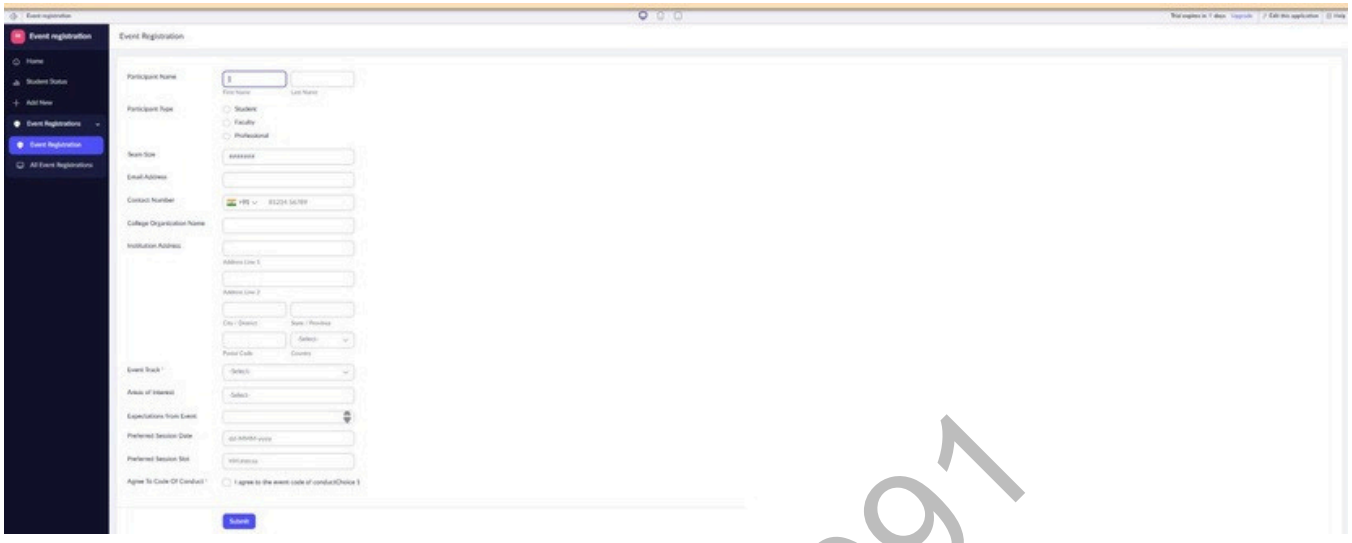

Fig 4. Live, user-facing Event Registration form ready to accept participant submissions.

Step 5 — Test the Form with Sample Data

The live form was completed and submitted with sample participant information to verify that mandatory fields, dropdown choices, and numeric/contact fields behaved correctly. Three sample registrations were entered in total to confirm the application could reliably handle multiple submissions.

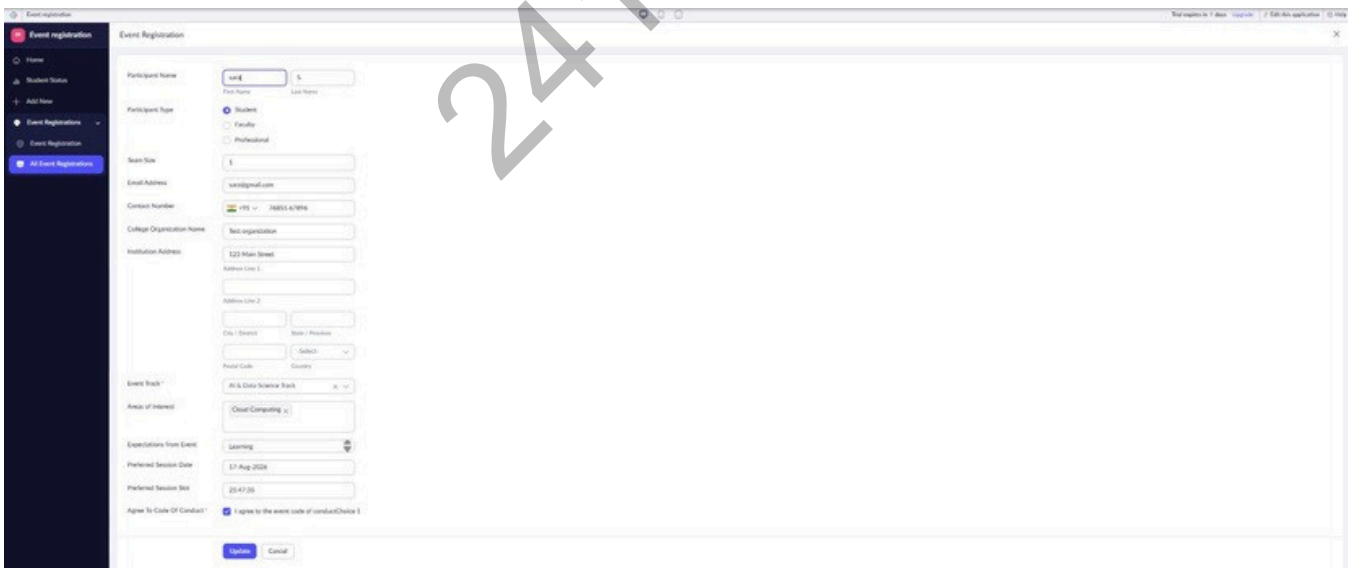

Fig 5. Sample registration data entered into the live form during testing.

Step 6 — Verify Records in the Database

The “AllEvent Registrations” reportwasopened to view the stored data in a spreadsheet-style grid, with each form field as a column and each submission as a row. All three test records were confirmed to be stored correctly under their respective columns, verifying that the live form was correctly connected to the underlying data store.

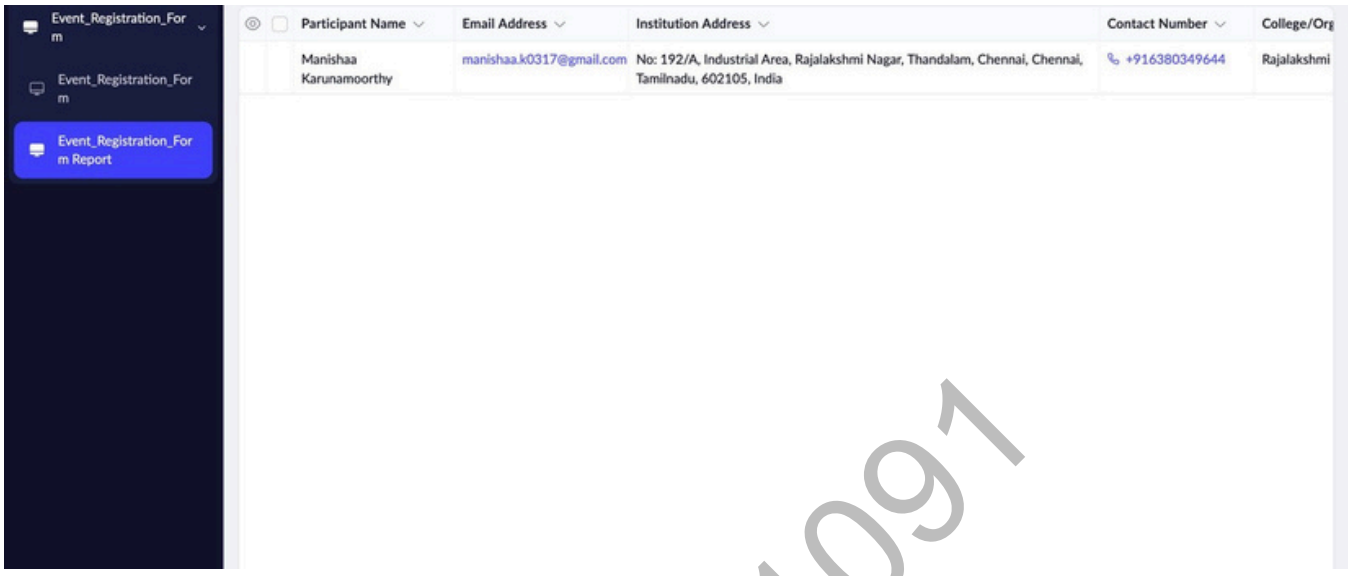

Fig 6. All Event Registrations grid confirming the three test records were stored correctly.

Data Modelling — Entity-Relationship Diagram

To support the registration form, the underlying data was structured as four related tables in Zoho Creator: Event Track, Participant, Event Session, and Event Registration. The diagram below shows the fields in each table and how the tables are linked using lookup relationships.

24140 1091

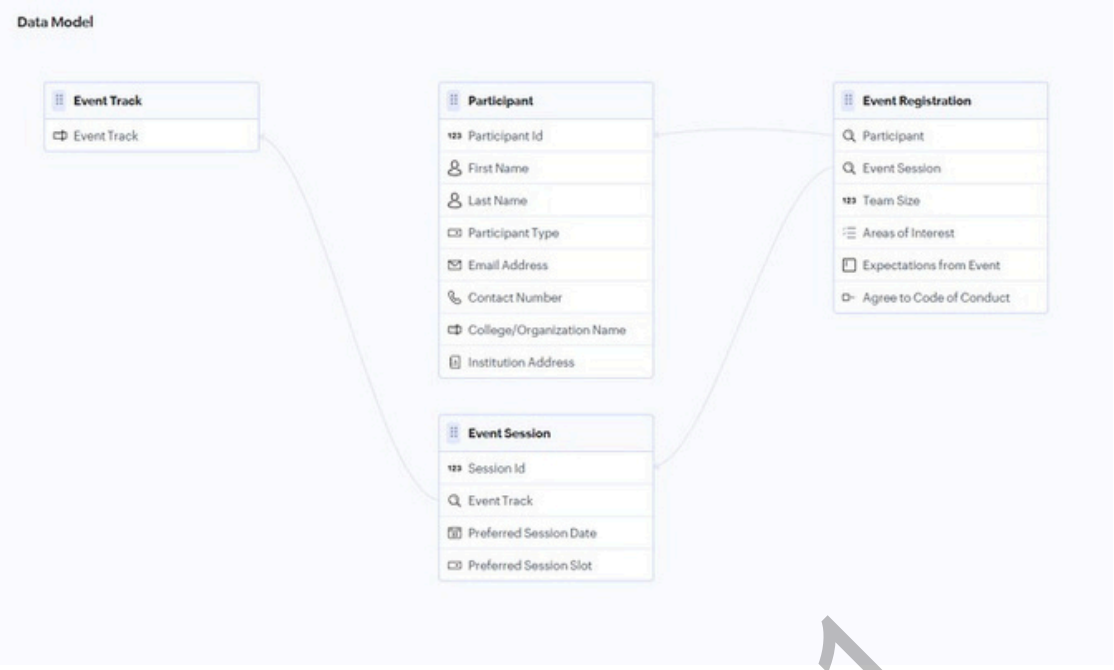

Fig 7. Entity-Relationship diagram of the Event Registration data model.

- **Event Track** stores the list of available event tracks/topics, each identified by an Event Track name, which participants can select from during session preference selection.
- **Participant** stores the details of each individual registering for the event: Participant Id, First Name, Last Name, Participant Type, Email Address, Contact Number, College/Organization Name, and Institution Address.
- **Event Session** defines the session-related preferences tied to a track: Session Id, a lookup to Event Track, Preferred Session Date, and Preferred Session Slot.
- **Event Registration** is the central linking table, connecting a Participant to an Event Session through lookup fields, and recording Team Size, Areas of Interest, Expectations from Event, and Agree to Code of Conduct.

This relational structure keeps participant details, track information, and session preferences independent of one another, with Event Registration acting as the linking table that ties a Participant to their chosen Event Session, which in turn is linked to an Event Track.

Result

The Event Registration application was successfully designed and deployed in Zoho Creator, with a four-table data model and a live form that correctly validated and stored all sample registrations.

Hence, the aim of designing a relational data model and building a corresponding form-based business application for event registration in Zoho Creator has been successfully achieved.
